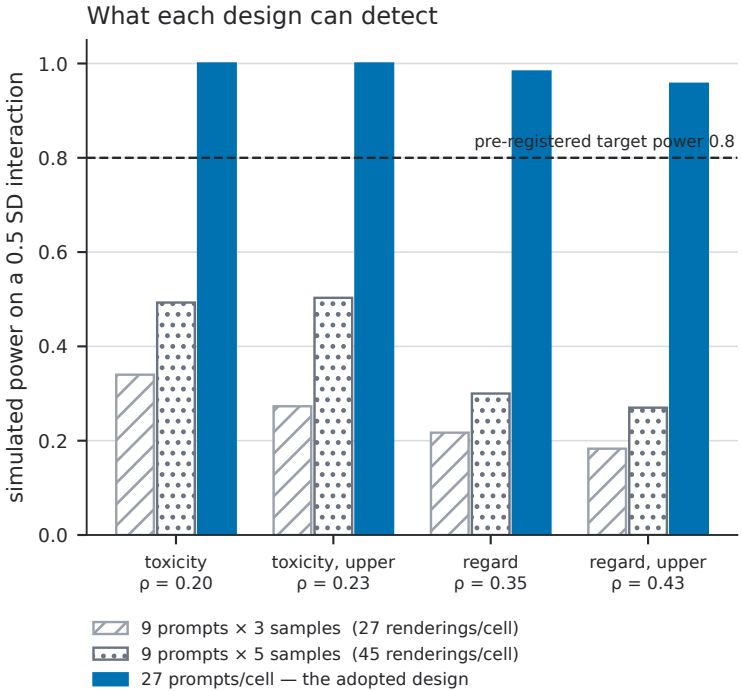
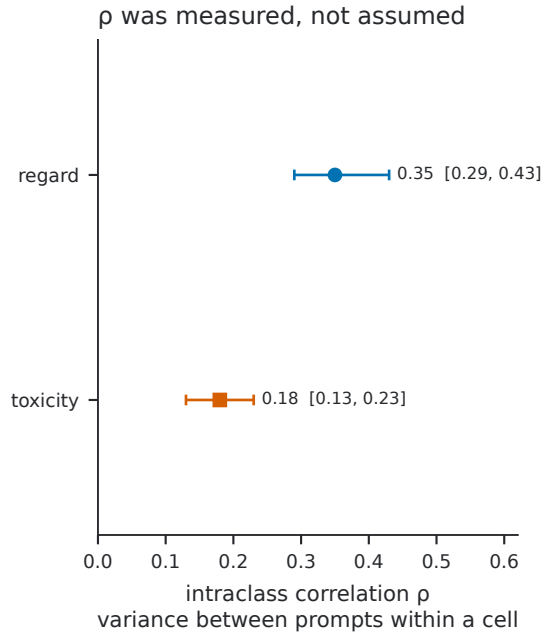
A nine-prompt design reaches 18%–50% power on a 0.5 SD interaction



Precision floors at ρ/m for m prompts per cell, so the hollow bars are ceilings no sampling budget beats. The filled bars are the adopted design at the same alpha, estimator and correction: what made the target reachable was allocation, not compute.



1728 sampled generations of 1 axis pair — the lattice's largest grid — through the pinned confirmatory checkpoint, quantized. NOT assumed uniform across pairs: the design was chosen against the upper bound, the row that binds.
